Study sampling design

Linear regression

$$Shannon_i = \beta_1 + \beta_2 HerbLayer_i + \varepsilon_i$$

$$\varepsilon_i \sim N(0, \sigma^2)$$

$$Shannon_i \sim N(\mu_i, \sigma^2)$$

$$\mu_i = \beta_1 + \beta_2 HerbLayer_i$$

Model validation

$$Shannon_i = \beta_1 + \beta_2 + HerbLayer_i + \varepsilon_i$$

$$\varepsilon_i \sim N(0, \sigma^2)$$

There is plot effect in the residuals!!

Alternative model

$$\begin{aligned}Shannon_i &= \beta_1 + \beta_2 HerbLayer_i + Plot_i + \varepsilon_i \\ &= (\beta_1 + Plot_i) + \beta_2 HerbLayer_i + \varepsilon_i\end{aligned}$$

$$\varepsilon_i \sim N(0, \sigma^2)$$

$$Shannon_i \sim N(\mu_i, \sigma^2)$$

$$\mu_i = \beta_1 + \beta_2 HerbLayer_i + Plot_i$$

Complete pooling VS no-pooling

Complete pooling

There is a single intercept for all the observations.

$$Shannon_i = \beta_1 + \beta_2 HerbLayer_i + \varepsilon_i$$

No pooling

There is a single intercept for each site.

$$Shannon_i = (\beta_1 + Plot_i) + \beta_2 HerbLayer_i + \varepsilon_i$$

Complete pooling VS no-pooling

Complete pooling

There is a single intercept for all the observations.

$$Shannon_i = \beta_1 + \beta_2 HerbLayer_i + \varepsilon_i$$

Partial pooling

The intercepts are correlated

No pooling

There is a single intercept for each site.

$$Shannon_i = (\beta_1 + Plot_i) + \beta_2 HerbLayer_i + \varepsilon_i$$

Linear mixed model

$$Shannon_{ij} = \beta_1 + \beta_2 HerbLayer_{ij} + a_i + \varepsilon_{ij}$$

$$a_i \sim N(0, \sigma^2_{Plot})$$

$$\varepsilon_{ij} \sim N(0, \sigma^2)$$

Linear mixed model

$$Shannon_{ij} = \beta_1 + \beta_2 HerbLayer_{ij} + a_i + \varepsilon_{ij}$$

$$a_i \sim N(0, \sigma^2_{Plot})$$

$$\varepsilon_{ij} \sim N(0, \sigma^2)$$

Random

Fixed Part: $\beta_1 + \beta_2 HerbLayer_{ij}$

Random Part: $a_i + \varepsilon_{ij}$

A “mixed model” has both fixed and random parts

Random versus Fixed Effects

Random effects are estimated with partial pooling, while fixed effects are not.

(Andrew Gelman and Jennifer Hill)

Varies by group

Variation estimated with **probability model**

Random intercept model

$$\begin{aligned}Shannon_{ij} &= \beta_1 + \beta_2 HerbLayer_{ij} + a_i + \varepsilon_{ij} \\ &= (\beta_1 + a_i) + \beta_2 HerbLayer_{ij} + \varepsilon_{ij}\end{aligned}$$

$$\varepsilon_{ij} \sim N(0, \sigma^2)$$

$$a_i \sim N(0, \sigma^2_{Plot})$$

Random intercept model

$$\begin{aligned}Shannon_{ij} &= \beta_1 + \beta_2 HerbLayer_{ij} + a_i + \varepsilon_{ij} \\ &= (\beta_1 + a_i) + \beta_2 HerbLayer_{ij} + \varepsilon_{ij}\end{aligned}$$

$$\varepsilon_{ij} \sim N(0, \sigma^2)$$

$$a_i \sim N(0, \sigma^2_{Plot})$$

It imposes a correlation structure on all the Shannon values of the same plot.

Random intercept model

$$\begin{aligned}Shannon_{ij} &= \beta_1 + \beta_2 HerbLayer_{ij} + a_i + \varepsilon_{ij} \\ &= (\beta_1 + a_i) + \beta_2 HerbLayer_{ij} + \varepsilon_{ij}\end{aligned}$$

$$\varepsilon_{ij} \sim N(0, \sigma^2)$$

$$a_i \sim N(0, \sigma^2_{Plot})$$

$$cor(Shannon_{ij}, Shannon_{ik}) = \varphi = \frac{\sigma^2_{Plot}}{\sigma^2_{Plot} + \sigma^2}$$

Protocol to fit a mixed model

1. Based on prior knowledge of the dependency structure in the data, select the random structure (i.e., the random effects) a priori.
2. Fit the model and investigate which covariates in the fixed part are important.
3. When optimal model has been found, present the numerical output and provide a graphic representation of the model fit.

Zuur, Alain.F, Joseph M. Hilbe, and Elena N Ieno (2013). A Beginner's Guide to GLM and GLMM with R: a frequentist and Bayesian perspective for ecologists, Highland Statistics

Our final random intercept model

$$\begin{aligned} \textit{Shannon}_{ij} = & 0.994 + 0.034\textit{HerbLayer}_{ij} \\ & - 0.031\textit{LitterCov}_{ij} + a_i + \varepsilon_{ij} \end{aligned}$$

$$\varepsilon_{ij} \sim N(0, 0.106^2)$$

$$a_i \sim N(0, 0.063^2)$$

Random intercept and slope model

$$\begin{aligned} \text{Shannon}_{ij} &= \beta_1 + \beta_2 \text{HerbLayer}_{ij} + a_i + b_i \text{HerbLayer}_{ij} + \varepsilon_{ij} \\ &= (\beta_1 + a_i) + (\beta_2 + b_i) \text{HerbLayer}_{ij} + \varepsilon_{ij} \end{aligned}$$

$$\varepsilon_{ij} \sim N(0, \sigma^2)$$

$$a_i \sim N(0, \sigma^2_{1, \text{Plot}})$$

$$b_i \sim N(0, \sigma^2_{2, \text{Plot}})$$

Generalized linear mixed models

$$Richness_{ij} \sim \text{Poisson}(\mu_{ij})$$

$$E(Richness_{ij}) = \mu_{ij} \quad \text{var}(Richness_{ij}) = \mu_{ij}$$

$$\mu_{ij} = \beta_1 + \beta_2 HerbLayer_{ij} + a_i$$

$$a_i \sim N(0, \sigma^2_{Plot})$$
